Use of end-tidal carbon dioxide monitoring to improve delivery of propofol in the neonatal intensive care unit. Hypoventilation is a known complication of anesthesia in neonates. End-tidal carbon dioxide (ETCO₂) monitoring can provide a rapid assessment of respiratory status. This study assessed the efficacy of using ETCO₂ monitoring to improve propofol administration in the neonatal intensive care unit. This prospective study involved 20 infants, 1-28 days old, admitted to a level III neonatal intensive care unit. The median (range) birth weight was 805 (544-2075) g and gestational age was 33 (24-42) weeks. The median (range) ETCO₂ before anesthetic induction was 36 (25-44) mmHg. Anesthesia was induced and maintained with propofol. End-tidal carbon dioxide levels were monitored continuously using a Licox ETCO₂ sensor and were displayed on the anesthesia machine. Four anesthesiologists (3 fellows and 1 senior) used ETCO₂ monitoring as a guide to adjust the propofol administration in real time. When the ETCO₂ rose above 55 mmHg, the propofol was quickly increased, and when the ETCO₂ fell below 25 mmHg, the propofol was decreased. Fifteen patients (75%) required increased propofol to maintain ETCO₂ levels above 25 mmHg during anesthesia. ETCO₂ monitoring effectively detected the onset of hypoventilation. End-tidal carbon dioxide monitoring is an effective way to ensure appropriate maintenance of ETCO₂ levels during anesthesia in the neonatal intensive care unit. Detection of Epstein-Barr virus DNA in peripheral blood cells of patients with nasopharyngeal carcinoma. Nasopharyngeal carcinoma (NPC) is a common malignancy in southern China. Immunosuppressive factors play an important role in its development. In this study, the effect of immunosuppressive cytokines on the expression of Epstein-Barr virus (EBV) genome and the level of EBV DNA in peripheral blood mononuclear cells (PBMC) in patients with NPC were examined. The proportions of CD8 82157476af
